charts are presented to show the pressure rise that is obtainable in an engine cooling installation with a typical airfoil type propeller speed fan the charts cover fans of the stator rotor rotor stator and rotor alone configurations with blades incorporating both the highly cambered 65 series blower blade sections and the conventional low cambered airfoil sections the effects of operation of a geared fan with rotational speeds limited by compressibility considerations and the effects of initial rotational inflow are indicated use of the charts to predict the pressure rise obtainable with any fan of the types considered is illustrated in a sample calculation

the identification of previously unrecognised inhomogeneous pressure distributions within the working chambers of screw spindle vacuum pumps provides new insights into their efficiency losses these chamber inhomogeneities which occur particular at low chamber pressures and high rotational speeds lead to increased gap mass flow rates due to locally increased pressures and also reduce the filling efficiency by decreasing the intake of mass during the filling process a novel one dimensional model is being developed to analyse these effects depending on the gas rarefaction the geometry and the gas surface interaction a closure problem arises which is solved separately using analytical solutions and results from the direct simulation monte carlo dsmc method the model is validated by experiments and three dimensional cfd simulations additionally transient cfd simulations are performed to investigate the chamber filling process with an expanding computational mesh based on these findings a dimensionless number is derived to quantify both the chamber inhomogeneity and the filling efficiency this enables an efficient integration of the new model into a chamber model simulation software a comparison of the simulation results with experimental data of a complete machine confirms the applicability of the model and leads to an excellent agreement
